OMNIVISION[™]

WS3235

Over Voltage Protection IC with Precision Adjustable Current Limit

Descriptions

The WS3235 features Input and Battery Over Voltage Protection as well as precision adjustable output Current Limit.

When input voltage exceeds input OVP threshold, the WS3235 will turn off internal MOSFET to disconnect IN to OUT. Current limit threshold can be programmed by external resistor. When OCP occurs and lasts for more than 180 μ s blanking time, the MOSFET will turn off. Once OCP reaches 16 times, the MOSFET will be permanently off unless the input power is recycled or \overline{EN} pin re-enabled. Battery OVP threshold is fixed 4.35V, and built-in 180 μ s blanking time could prevent false triggering. When the battery OVP occurs for 16 times, the MOSFET will turn off permanently unless the input power is recycled or \overline{EN} pin re-enabled.

The WS3235 is available in DFN2x2-8L package. Standard product is Pb-Free and Halogen-Free.

Features

- Programmable OCP
- Fixed OVP Threshold
 - WS3235D : 6.8V
 - WS3235D58 : 5.85V
 - WS3235D62 : 6.25V
- Battery OVP : 4.35V
- Maximum Input Voltage: 30V
- Input Over Voltage Turn Off Time: 0.1µs
- Over Temperature Protection
- High Immunity of False Triggering Under Transients
- High Accuracy Protection Thresholds
- Warning Indication Output

Applications

- Cellular Phones and Digital Cameras
- PDAs and Smart Phones
- Portable Instruments

Operation Information

Power Up

The WS3235 has a threshold of 2.7V power on reset (POR). The hysteresis of the POR threshold is 100mV. The IC is off before the input voltage reaches the POR threshold. When the input voltage is over the POR threshold, the WS3235 soft-start which can reduce the inrush current will be activated after 8ms delay. Any transients at the input during a hot insertion of the power supply will be settled down before the IC starts to operate.

Enable Control

The WS3235 offers a chip enable (\overline{EN}) input. There is an internal pull-down resistor in the \overline{EN} pin. Pull this pin to low (<0.4V) or leave it floating to enable the IC and force it to high (>1.5V) to disable the IC.

Over Temperature Protection (OTP)

As soon as the junction temperature reaches 155°C, the WS3235 will turn off the MOSFET. And the IC will not turn on the MOSFET unless the junction temperature is cooled down 30°C.

Input Over Voltage Protection

The WS3235 input OVP threshold is set by the internal resistors. When the input voltage exceeds the threshold, the MOSFET is turned off in 0.1µs, removing power from the system. The hysteresis of the input OVP threshold is 100mV. When the input voltage returns to normal operation voltage range, the WS3235 will turn on the MOSFET.

Battery Over Voltage Protection

The battery OVP threshold voltage is set at 4.35V with 30mV hysteresis typically. To prevent transient voltage from triggering the battery OVP, the WS3235 has a built-in 180 μ s blanking time. If the battery OVP situation still exists after 180 μ s, the MOSFET will be turned off and the WRN pin indicates a LOW signal. The MOSFET will be turned off permanently if the battery OVP event occurs 16 times which is recorded by the counter. Reset input power or \overline{EN} pin can turn on the MOSFET.

Over Current Protection (OCP)

The WS3235 OCP threshold can be set by an external resistor:

$$I_{\rm OCP} = \frac{25000}{R_{\rm ILIM}}$$

The WS3235 has a built-in 180µs delay time to prevent any transient noise from triggering the OCP. If the OCP situation lasts for 180µs, the MOSFET will be turned off and the $\overline{\text{WRN}}$ pin indicates a LOW signal. After 64ms recover delay, the MOSFET will be turned on again. When the OCP occurs 16 times, the MOSFET will be turned off permanently unless the input power or the $\overline{\text{EN}}$ pin is reset.

Warning Indication Output

The WRN pin is an open-drain output that indicates a LOW signal when protection event occurs (Input OVP, Output OCP and Battery OVP). When the protection events are released and then the WRN pin indicates a HIGH signal.

9

Application Information

Capacitors Selection

Input over shoot voltage will be reduced by increasing the input capacitance, but in the meantime, it will increase the inrush current of input. The input over shoot voltage range which can be influenced by AC adapter hot-plugging is 1.5 to 2 times of the input voltage. The recommended capacitance on input and output is 1μ F, and the rated voltage should be higher than at 1.5 to 2 times of the operation voltage.

R_{VB} Selection

Battery OVP threshold error is determined by R_{VB} . Decrease the R_{VB} will reduce the battery OVP threshold error, but this will also increase the discharge current when the battery is reversed, which will easily cause reliability problems. To balance the negative factors, the resistance of $10k\Omega$ to $200k\Omega$ is allowed for R_{VB} .

PCB Layout Consideration

Following guidelines:

- To reduce noise coupling, locate C_{IN} and C_{OUT} as close to the IC as possible and get them connect to ground plane.
- 2. R_{LIMIT} should be placed closed to ILIM pin as near as possible and connect to ground plane.
- 3. Keep main current traces as short and as wide as possible.
- 4. The exposed pad should be connected to a strong ground plane for heat sink.
